ESDL Language Reference
ESDL Language Overview

ESDL Language Overview

ESDL (Enterprise Service Description Language) is a methodology that helps you develop and manage web-based query interfaces quickly and consistently.

Dynamic ESDL takes an interface-first development approach. It leverages the ESDL Language to create a common interface "contract" that both Roxie Query and Web interface developers will adhere to. It is intended to allow developers to create production web services, with clean interfaces that can evolve and grow over time without breaking existing applications.

ESDL's built-in versioning support helps ensure compiled and deployed applications continue to operate while changes are made to the deployed service's interface for new functionality.

ESDL’s ability to define and reuse common structures helps maintain consistent interfaces across methods.

The Dynamic ESDL service is built to scale horizontally, and hooks are provided to add custom logging and security to help create fully "productionalized" web services.

Once a service is deployed, application developers and end-users can consume the service using REST, JSON, XML, SOAP, or form encoded posts. Dynamic ESDL provides quick and easy access to a WSDL, live forms, sample requests and responses, and testing interfaces to allow developers to test logic changes, data changes, or new features, as well as to interact with the service directly using SOAP, XML, or JSON.
ESPstruct

ESPstruct is a set of elements grouped together under one name. These elements, known as members, can have different types and different lengths. Structures can be nested and support inheritance.

Example:

ESPstruct NameBlock
{
    string FirstName;
    string MiddleName;
    string LastName;
    int Age;
};

ESPstruct NameBlockExtended:NameBlock
{
    string SSN;
    string partyAffiliation;
};
**ESPrequest**

The request structure for a method. ESPrequests can be nested and support inheritance.

**Example:**

```csharp
ESPrequest MyQueryRequest
{
  string FirstName;
  string MiddleName;
  string LastName;
  string Sortby;
  bool Descending(false);
};

ESPrequest MyQueryRequestExtended:MyQueryRequest
{
  string SSN;
};
```
ESDLPurpose

The response structure for a method. ESPresponeses can be nested and support inheritance.

Example:

```csharp
ESPresponse MyQueryResponse
{
    string FirstName;
    string MiddleName;
    string LastName;
}

ESPresponse MyQueryResponseExtended:MyQueryResponse
{
    string SSN;
    string partyAffiliation;
}
```
**ESPaarray**

A structure for unbounded arrays. Arrays support inheritance and can be nested.

Either \([\text{max\_count\_var}(k)]\) or \([\text{max\_count\_var}(k)]\) is required for an ESPArray when \(k>1\).

**Example:**

```plaintext
ESPstruct NameBlock
{
    string FirstName;
    string MiddleName;
    string LastName;
    int Age;
};
[max\_count(20)] ESParray <ESPstruct NameBlock, Name> Names;
```

This results in something like:

```xml
<Names>
  <Name>
    <FirstName>James</FirstName>
    <MiddleName>Joseph</MiddleName>
    <LastName>Deerfield</LastName>
    <Age>42</Age>
  </Name>
  <Name>
    <FirstName>Emily</FirstName>
    <MiddleName>Kate</MiddleName>
    <LastName>Constance</LastName>
    <Age>33</Age>
  </Name>
</Names>
```

See Also: `max\_count\_var`, `max\_count`
ESPenum

A structure containing an enumerated value.

Example:

ESPenum EyeColors : string
{
    Brn("Brown"),
    Blu("Blue"),
    Grn("Green"),
};

ESPstruct Person
{
    string FirstName;
    string MiddleName;
    string LastName;

    ESPenum EyeColors EyeColor("Brown"); //provides a default value
};
ESPinclude

ESPinclude allows you to include an external ESDL file. This is similar to the #include statement.

Example:

ESPinclude(commonStructures);
ESPservice

This defines an ESP web service interface. Once defined, this interface definition can be assigned (bound) to a Dynamic ESDL-based ESP Service.

An ESPservice should contain one or more method definitions.

Example:

```
ESPservice [auth_feature("AllowMyService")] MyService {
    ESPmethod MyMethod1(MyMethod1Request, MyMethod1Response);
    ESPmethod MyMethod2(MyMethod2Request, MyMethod2Response);
};
```
**ESPmethod**

This defines a method definition you can reference in an ESPservice structure. The method definition should contain references to a previously defined ESPrequest and ESPresponse.

**Example:**

```plaintext
ESPservice MyService
{
    ESPmethod MyMethod1(MyMethod1Request, MyMethod1Response);
    ESPmethod[
        auth_feature("AllowMyMethod2"),
        description("MyMethod Two"),
        help("This method does everything MyMethod1 does plus a few extra features"),
        min_ver("1.2")
    ]
    MyMethod2(MyMethod2Request, MyMethod2Response);
}
```
boolean / bool

A boolean or logical data type having one of two possible values: true (1) or false (0).

Example:

```plaintext
boolean includeFlag;
bool includeMore;
```
**string**

A data type consisting of sequence of alphanumerical characters.

**Example:**

```plaintext
string FirstName;
```
**int**

An integer value.

**Example:**

```plaintext
int Age;
```
int64

A 64-bit integer value

Example:

int64 Iterations;
**float**

A 4-byte floating point or real number.

**Example:**

```plaintext
float Temperature;
```
**double**

An 8-byte floating point or real number.

**Example:**

```c
double Temperature;
```
binary

A data type containing binary data, similar to a BLOB.

Example:

```plaintext
binary RetinaScanSample;
```

ESDL Language Reference
ESDL Attributes

ESDL Attributes

You can use ESDL attributes to extend and override the default behavior of an ESDL definition. For example, adding a `max_len(n)` to a string defines the string will only need to store a certain number of characters.

Many attributes are treated as hints that may have more effect on some implementations than others. For example, `max_len(n)` will affect generated ECL code, but is ignored when generating C++.
max_len (n)

The `max_len` attribute specifies the field length for ECL string field.

**Example:**

```ecl
[max_len(20)] string City;
```

It means that in ECL, City field is a fixed length of 20 chars. For integer type, the `max_len` means the maximum size in bytes for the integer (`8*max_len` bits integer).

**Example:**

```ecl
[max_len(3)] int Age;
```

This generates ECL code:

```ecl
integer3 Age{xpath('Age')};
```

This attribute works for ESPenum type, too. The ECL type is also string.

```ecl
[max_len(2)] ESPenum StateCode State;
```

Here the StateCode is 2-char state code enumeration.

This attribute can also be used for ESPstruct, ESPrequest, ESPresponse:

```ecl
ESPstruct [max_len(1867)] IdentitySlim : Identity
{
  ...
};
```

This generates ECL code:

```ecl
export t_MyQuery := record (share.t_Name), MAXLENGTH(1867)
{
  ...
};
```

The ECL option `MAXLENGTH` helps ECL engine better manage memory.

This does not affect the type in the XSD/WSDL. ESP ignores this attribute when generating the schema. The type for a string is `xsd:string` which has no length limit. Therefore, the schema stays the same if the field length changes in the Roxie query.
ecl_max_len (n)

This `ecl_max_len` attribute tells the ECL generator to use ECL `maxlength` instead of the regular field length.

**Example:**

```ecl
[ecl_max_len(50)] string CompanyName;
[max_len(6)] string Gender;
```

The generated ECL code is:

```ecl
string CompanyName { xpath("CompanyName"),maxlength(50) };
string6 Gender { xpath("Gender") };
```

**Note:** when both `max_len` and `ecl_max_len` are specified, `ecl_max_len` is used and `max_len` is ignored.
ecl_name ("name")

The ecl_name attribute specifies the field name in generated ECL code. By default, the field name in ECL is the same as the name defined in ECM. However, in some cases, the name could cause issues in ECL. For example, keywords in ECL cannot be used as a field name.

Example:

```
[ecl_name("_export") string Export;
[ecl_name("_type") string Type;
```

Here, both EXPORT and TYPE are ECL keywords and cannot be used as ECL field names. We use ecl_name to tell the esdl2ecl process to generate acceptable names.
**counter and count_val**

These two attributes are used to help ESP calculate the record count of the response.

`counter` counts the number of children of the nodes. When the node is an array, it is the same as the number of items in the array.

`count_val` will use the value of the node as record count. Field `RecordCount` is implicitly marked as `count_val`.

When an response has multiple `counter`, `count_val`, the sum of the values is returned as record-count.

**Example:**

```plaintext
[counter] ESPArray<MyRecord, Record> Records;
[count_val] int TotalFound;
```
max_count

The `max_count` attribute is used to specify the expected max items in a dataset (ESPArray).

**Example:**

```esdl
[max_count(20)] ESPArray <ESPstruct MYRecord, Record> Records;
```

See Also: ESPArray, max_count_var
**max_count_var**

The `max_count_var` attribute is used to specify a variable (an ECL Attribute) containing the value of the expected max items in a dataset (ESParray).

**Example:**

```plaintext
[max_count_var("iesp.Constants.JD.MaxRecords")]] ESParray <ESPstruct MYRecord, Record> Records;
```

The ECL developer defines the constant `iesp.Constants.JD.MaxRecords` rather than hard coding the max count value in the ESDL.

See Also: ESParray, max_count
**ecl_null (n | string)**

The `ecl_null` attribute tells ESP to remove the field altogether if the field's value is `n` or `string`. This provides a means to remove a field completely when there is no data for it.

**Example:**

```plaintext
[ecl_null(0)] int Age;
[ecl_null("false") bool IsMatch;
```

Age 0 means there is no Age data for this person. So, if Age is 0, the `<Age>` tag is not returned.

Without this attribute, `<Age>0</Age>` would be returned.

For the second example, a bool value of `false`, returned as a string, is treated as null and therefore the tag is not returned.
leading_zero(n)

The `leading_zero` attribute adds zero(s) to the field value to so that the total length is \( n \).

Example:

```
ESP struct Date
{
    [leading_zero(4)] Year;
    [leading_zero(2)] Month;
    [leading_zero(2)] Day;
};
```

So the Date will always have a 4-digit Year and a 2-digit Month and a 2-digit Day.
**ecl_hide**

The `ecl_hide` attribute hides the field from ECL (that is, the field is removed when generating the ECL code). This is used for some special cases.

**Example:**

```cpp
ESPstruct Relative
{
    [ecl_hide] ESPArray<ESPstruct Relative, Relative> Relatives;
};
```

In this case, the Relative structure is defined in a recursive manner, and ECL does not support such a construct. Therefore, we use `ecl_hide` to avoid the recursive definition in ECL.

Sometimes a field is hidden from ECL for other reasons. In these cases, `ecl_hide` is not needed.
ecl_type ("type")

The ecl_type attribute defines the field type in ECL.

**Example:**

```java
[ecl_type("Decimal10_2")]
```

double RetailPrice;

ESDL does not have a monetary type, so we use ecl_type to define it.
**ecl_keep**

The `ecl_keep` attribute keeps the field in the generated ECL even though this field would have been hidden without this attribute.
min_ver

The min_ver attribute allows you to define the minimum (earliest) version where a field is visible. Requests using a prior version will not have access to the field.

Example:

```
[min_ver("1.03")]
bool IsValid;
```
max_ver

The max_ver attribute allows you to define the maximum (latest) version where a field is visible. Requests using a later version will not have access to the field.

Example:

```plaintext
[max_ver("1.04")] bool IsValid;
```
ping_min_ver

Dynamic ESDL services automatically add a ping method to your service for monitoring connectivity to the service.

The ping_min_ver attribute on a service allows you to define the minimum (earliest) version where the ping method is visible. The ping method is not visible to versions lower than the ping_min_ver

Example:

```
[ping_min_ver("1.03")]
```
depr_ver

The depr_ver attribute allows you to declare a field's end of life version. The field is deprecated at the specified version number. Requests using that version or any subsequent version will not have access to the field.

Example:

[depr_ver("1.04")] bool IsValid;
get_data_from

The get_data_from attribute allows you to specify that a field gets its data from another variable. This supports code reuse when complex versioning changes are made.

Example:

```csharp
ESPResponse RoxieEchoPersonInfoResponse
{
    ESPstruct NameInfo Name;
    string Var1;
    [get_data_from("Var1")]
    string Var2;
};
```

In the example above, the query returns the data in Var1 then the service puts the data into the Var2 field and sends that in the response to the client.

In this example both Var1 and Var2 are in the response to the client. Typically, Var1 and Var2 are in non-overlapping versions so only one will be in the response depending on the version specified.

Since the get_data_from attribute supports complex data types, such as an ESPstruct, the fields do not have to be limited to string types.
optional

The optional attribute allows you to specify that a field is optional and is hidden or not depending on the absence or presence of a URL decoration.

When a field has an optional attribute, the field is visible only when the option appears on the URL. But when the option starts with an exclamation point (!), then the field is hidden only if the option is in the URL.

Example:

```esdls
ESPRequest RoxieEchoPersonInfoRequest
{
    ESPstruct NameInfo Name;
    string First;
    string Middle;
    string Last;
    [optional("dev")] string NickName;
    [optional("!_NonUS_")] string SSN;
};
```

Assuming the service is running on a server with the hostname of example.com and the service binding is set to 8003:

If the URL is

```http
http://example.com:8003/
```

then SSN is visible and NickName is hidden;

If the URL is

```http
http://example.com:8003/?dev
```

then SSN and NickName are both visible

If the URL is

```http
http://example.com:8003/?dev&_NonUS_
```

then NickName is visible and SSN is hidden.

If the URL is

```http
http://example.com:8003/?_NonUS_
```

then both NickName and SSN are hidden.
help

The help attribute (valid only for an ESPMethod) allows you to specify some additional text to display on the form that is automatically generated to execute a method.

Example:

```cpp
ESPService MyService
{
    ESPMethod MyMethod1(MyMethod1Request, MyMethod1Response);
    ESPMethod
    [
        description("MyMethod Two"),
        help("This method does everything MyMethod1 does plus a few extra features"),
        min_ver("1.2")
    ]
    MyMethod2(MyMethod2Request, MyMethod2Response);
}
```
**description**

The `description` attribute (valid only for an ESPMethod) allows you to specify some additional text to display on the form that is automatically generated to execute a method.

**Example:**

```python
ESPservice MyService
{
    ESPmethod MyMethod1(MyMethod1Request, MyMethod1Response);
    ESPmethod
    [
        description("MyMethod Two"),
        help("This method does everything MyMethod1 does plus a few extra features"),
        min_ver("1.2")
    ]
    MyMethod2(MyMethod2Request, MyMethod2Response);
}
```
version and default_client_version

The version and default_client_version attributes (valid only for an ESPService) allow you to specify the version to use when a version is not explicitly specified in the request.

The default_client_version is used for API requests in SOAP format if the client doesn't specify the version. The version is used for requests coming from a web browser without a version decoration in the URL.

These attributes provide better API backward compatibility while allowing API developers to see the latest interface using a browser.

If default_client_version is higher than version, the service uses default_client_version for all requests that don't specify a version.

Even though defaults can be specified for a service, you should still encourage API developers to specify a version in requests to ensure compatibility between their application and the service.

Example:

```c
ESPservice [version("0.02"), default_client_version("0.01")] EsdlExample
{
    ESPmethod EchoPersonInfo(EchoPersonInfoRequest, EchoPersonInfoResponse);
    ESPmethod RoxieEchoPersonInfo(RoxieEchoPersonInfoRequest, RoxieEchoPersonInfoResponse);
}
```
auth_feature

The auth_feature attribute (valid only for an ESPService or ESPMethod) allows you to specify a means to verify a user's permission to execute a method.

In order to enable this feature, your system must be configured to use a form of security that supports feature level authentication, such as LDAP security included in the Community edition of the platform. Once LDAP is configured, you would add the tag name provided as the value for the `authFeature` attribute to the feature level authentication list in the Security section of ECL Watch. Then you would set permissions for users and/or groups.

If you are using a third-party Security Manager plugin, consult their documentation for details on adding the tag name to their security configuration.

The `auth_feature` attribute is required for every method, but can be specified at the ESPService level to apply to all methods within a service. You can override for an individual method by setting the attribute at a method level.

Setting `auth_feature("NONE")` means no authentication is needed. Setting `auth_feature("DEFERRED")` defers the authentication to the business logic in the ESP developer's method implementation logic.

Example:

```esdl
ESPService MyService [auth_feature("NONE")]
{
    ESPmethod MyMethod1(MyMethod1Request, MyMethod1Response);
    ESPmethod
    [
        description("MyMethod Two"),
        auth_feature("AllowMyMethod2"),
        help("This method does everything MyMethod1 does plus a few extra features"),
        min_ver("1.2")
    ]
    MyMethod2(MyMethod2Request, MyMethod2Response);
}
```
